

Search Strategy and Quality Criteria

Introduction

For our project, we are working with **Thuiszorg Totaal**. We are researching how AI could help the company, mainly by automating scheduling and notifications.

For example, AI could potentially help with planning employee schedules, handling changes in schedules, and sending notifications to employees or clients.

To research this properly, we need good and reliable sources. Our AI tool should also be able to search for useful information and help us decide which sources are good enough to use.

Search Strategy

We will search for information that is directly connected to our project.

Some examples of search terms are:

- AI scheduling in healthcare
- AI scheduling in home care
- Automated employee scheduling
- AI for home-care companies
- Automatic notifications in healthcare
- AI automation for SMEs
- AI in Dutch healthcare
- AI scheduling and GDPR

We will mainly look for information from:

- Google Scholar
- Government websites
- European Union sources
- Research organizations
- Healthcare organizations
- Reliable business and technology websites

We can also use information from AI/software companies when we want to understand how a specific technology works. However, we should be careful because companies may present their own products positively.

Selection Criteria

Before using a source, we should decide whether it is suitable for our research.

Include a source when:

- It is relevant to our research.
- It is related to AI, scheduling, notifications, healthcare or SMEs.
- The author or organization is known.
- The information can be checked.
- It contains useful information or evidence.
- It is reasonably recent.
- It is relevant to the Netherlands or Europe when possible.

Exclude a source when:

- It is not relevant to our research.
- The author or organization is unknown.
- We cannot check where the information came from.
- It contains mainly opinions without evidence.
- The information is outdated.
- It makes strong claims without providing evidence.
- It is mainly advertising a product without providing reliable evidence.

Quality Criteria

After selecting a source, we need to check its quality.

We will use five main criteria.

Criteria	What we check	Points
Relevance	Is it related to our research about AI, scheduling, notifications or home care?	25
Reliability	Is the author or organization trustworthy?	25
Evidence	Does the source provide research, data, examples or references?	20
Recency	Is the information recent enough for our topic?	15

Criteria	What we check	Points
Context	Is it relevant to healthcare, SMEs, the Netherlands or Europe?	15
Total		100

Source Scoring

After checking the source, our tool can give it a score out of 100.

80–100 points = Very good source

We can use the source in our research.

60–79 points = Good source

We can use it, but we should check its limitations.

40–59 points = Weak source

We should try to find a better source.

Below 40 points = Do not use

For example, a recent research paper about **AI scheduling in European home-care organizations** would probably receive a high score because it is reliable and very relevant to Thuiszorg Totaal.

A random blog saying "**AI will completely change employee scheduling**" without research or evidence would receive a low score.

How Our AI Tool Can Use This

Our AI tool should follow a simple process:

Search → Check → Score → Select

First, the tool searches for information using keywords related to our research.

Second, it checks whether the source meets our selection criteria.

Third, it gives the source a quality score.

Finally, good sources are selected for our research and weak sources are rejected.

The final decision should still be checked by a team member because AI can make mistakes.
